1 MODBUS FUNCTIONS AND RESOURCES

Modbus is a client/server communication protocol for communication between *network* connected devices. Modbus devices communicate using a master-slave technique in which only one device (the master) can send queries. The other *network* devices (slaves) respond by supplying the data requested by the master or by taking the action requested in the query. A slave is any device connected to the *network* which processes information and sends its output to the master using the Modbus protocol.

Masters can *address* individual slaves or send broadcast messages to the entire *network* whereas slaves only return a response to queries addressed to them individually from masters.

The Modbus standard used by Eliwell uses the RTU protocol for data transmission.

1.1 Data format (RTU)

The code model used defines the structure of the messages transmitted on the *network* and the way this information is decoded. The type of code is usually selected according to specific parameters (baud rate, parity, etc..), Some devices only support certain code models but the same one must be used for all the devices connected to a Modbus *network*.

The protocol uses the RTU binary method with the bytes containing:

8 data bits, configurable parity bit (see parameter **PtY**, *default* value= Even),

1 configurable stop bit (see parameter **StP**, *default* value = 1b)

NOTE: the baud rate must be set to 9600 bauds.

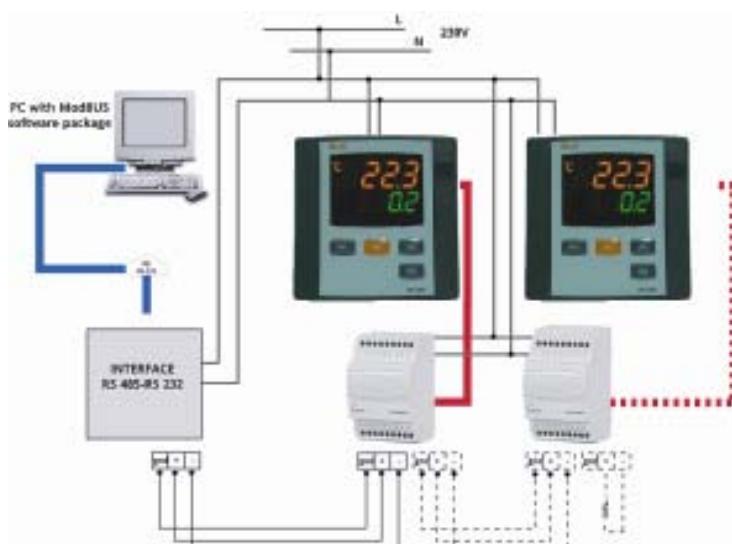

Parameters can be set so that the *device* is fully configurable

Parameters can be changed from the:

- Keyboard
- copy Card
- sending the data via the ModBus protocol straight to a single device or by sending a broadcast message using *address* 0 (broadcast *address*)

1.2 Network

Diagram of
Modbus
connection to
multi-unit

PC/Interface connection	RS232 cable
Device/Bus Adapter connection	5-path connector TTL cable (30cm) (other sizes/lengths available)
Bus Adapter	BA150
Bus Adapter/Interface connection	RS485 cable shielded and twisted (e.g.: Belden cable model 8762)

1.3 Modbus functions available and data area

Modbus command	Description of command								
3	Reading multiple registers A maximum of 60 consecutive registers can be read. Parameters belonging to two different non-consecutive blocks cannot be read using a single command.								
16	Writing multiple registers A maximum of 60 consecutive registers can be written								
43	Reading instrument ID The following 3 fields can be read: <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>Field code</th><th>Field description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Manufacturer ID ("Invensys")</td></tr> <tr> <td>1</td><td>Instrument model ID ("003E_0402")</td></tr> <tr> <td>2</td><td>Instrument version ID ("00FB_0001")</td></tr> </tbody> </table>	Field code	Field description	0	Manufacturer ID ("Invensys")	1	Instrument model ID ("003E_0402")	2	Instrument version ID ("00FB_0001")
Field code	Field description								
0	Manufacturer ID ("Invensys")								
1	Instrument model ID ("003E_0402")								
2	Instrument version ID ("00FB_0001")								

1.4 Address configuration

The device **address** in a ModBus message comprises one byte and consists of the family code and the device code, indicated by dBA, made up of parameters FAA and dEA respectively.

The Device **Address** therefore consists of two nibbles:

- **dEA:** low nibble
- **FAA:** high nibble

To calculate the **address** using parameters FAA and dEA:

$$\text{dBA} = \text{FAA} \times 16 + \text{dEA}$$

For example: **address** 00 01 (dEA=01; FAA=00)

Address 0 is used for broadcast queries that are recognized by all the slaves. Slaves do not respond to broadcast queries.

DEVICE CONFIGURATION PARAMETERS			
Par.	Description	Value	Limits
PtS	Protocol selection	t	t=Televis d=modbus
dEA	Device address	1	0...14
FAA	Family address	0	0...14
PtY	Modbus parity bit (none, Even, odd)	E	n=none, E=Even, o=odd
Stp	Setting stop bit (1b,2b)	2b	1b 2b

Note: If parameters **PtS**, **PtY** and **Stp** are changed, the controller must be turned off and then on again after they are changed to operate correctly.

1.5 Table of addresses

1.5.1 Description of parameters

The **address tables** contain the necessary read, write and decode information for each single resource accessible in the device.

There are two tables:

- the **parameter** table contains all the device configuration parameters stored in the non-volatile memory of the device.
- the **client table** includes all the I/O and alarm status resources available in the volatile memory of the device.

Description of columns:

INDEX For the **parameter** table this value represents the order in which the parameter is displayed in the device menu. For the **client table** this value is not significant.

FOLDER This indicates the **folder** in which the **parameter** can be seen. the meanings of the values depend on the model:

Value

- | | |
|---|---|
| 0 | Parameter not visible |
| 1 | Parameter visible at level 1 of menu,
You can access the parameters
in this level once you have typed
Password 1 into the device |
| 2 | Parameter visible at level 2 of menu, |

		You can access the parameters in this level once you have typed Password 2 into the device 3 Parameter visible at both menu levels																								
LABEL	Indicates the <i>label</i> used to display the parameters in the device menu.																									
ADDRESS	The whole part represents the MODBUS register <i>address</i> containing the value of the resource to read or write in the instrument. The value after the comma indicates the position of the most significant bit of the data in the register; if it is not stated, it equals zero. This information is always provided when the register contains more than one data element and it is important to understand which bits actually represent the data element (the size of the data indicated in the DATA SIZE column is also considered). Since Modbus registers are the size of one WORD (16 bits), the <i>index</i> after the comma can vary from 0 (least significant bit –LSb–) to 15 (most significant bit –MSb–). Examples (in binary representation the least significant bit is the rightmost bit)																									
	<table border="1"> <thead> <tr> <th>ADDRESS</th><th>Register contents</th><th>DATA SIZE</th><th>value</th></tr> </thead> <tbody> <tr> <td>8806</td><td>1350 (0000010101000110)</td><td>WORD</td><td>1350</td></tr> <tr> <td>8806</td><td>1350 (0000010101000110)</td><td>Byte</td><td>70</td></tr> <tr> <td>8806,8</td><td>1350 (0000010101000110)</td><td>Byte</td><td>5</td></tr> <tr> <td>8806,14</td><td>1350 (0000010101000110)</td><td>1 bits</td><td>0</td></tr> <tr> <td>8806,7</td><td>1350 (0000010101000110)</td><td>4 bits</td><td>10</td></tr> </tbody> </table>	ADDRESS	Register contents	DATA SIZE	value	8806	1350 (0000010101000110)	WORD	1350	8806	1350 (0000010101 000110)	Byte	70	8806,8	1350 (0000010101000110)	Byte	5	8806,14	1350 (0000010101000110)	1 bits	0	8806,7	1350 (0000010101000110)	4 bits	10	
ADDRESS	Register contents	DATA SIZE	value																							
8806	1350 (0000010101000110)	WORD	1350																							
8806	1350 (0000010101 000110)	Byte	70																							
8806,8	1350 (0000010101000110)	Byte	5																							
8806,14	1350 (0000010101000110)	1 bits	0																							
8806,7	1350 (0000010101000110)	4 bits	10																							
	Please note: when the register contains more than one data element, proceed as follows for the write operation: read the current value of the register modify the bits that represent the relevant resource write the register																									
R/W	Indicates the possibility of reading or writing the resource:																									
	<table> <tr> <td>R</td><td>the resource is read only</td></tr> <tr> <td>W</td><td>the resource is write only</td></tr> <tr> <td>RW</td><td>the resource is read/write</td></tr> </table>	R	the resource is read only	W	the resource is write only	RW	the resource is read/write																			
R	the resource is read only																									
W	the resource is write only																									
RW	the resource is read/write																									
DATA SIZE	Indicates size of the data in bits.																									
	<table> <tr> <td>WORD</td><td>=</td><td>16 bits</td></tr> <tr> <td>Byte</td><td>=</td><td>8 bits</td></tr> <tr> <td>"n" bit</td><td>=</td><td>0...15 bits depending on "n"</td></tr> </table>	WORD	=	16 bits	Byte	=	8 bits	"n" bit	=	0...15 bits depending on "n"																
WORD	=	16 bits																								
Byte	=	8 bits																								
"n" bit	=	0...15 bits depending on "n"																								
CPL	When "Y" is indicated, the value read by the register requires conversion because the value represents a number with a sign. In other instances, the value is always positive or null. For the conversion, see below: if the value of the register is between 0 and 32767, the result is the value itself (zero and positive values) if the value of the register is between 32768 and 65535, the result is the value of the register - 65536 (negative values)																									
RANGE	This describes the <i>range</i> of values permitted for the parameter. It can be correlated with other device parameters (indicated with parameter <i>label</i>).																									
DEFAULT	Indicates the factory set value for the standard model of the device.																									
EXP	This is the multiplier <i>index</i> that must be applied to convert the value read by the register to the values indicated in the RANGE and DEFAULT column in order to convert them into the final values based on the unit of measurement indicated in the M.U column. The multiplier is calculated using the exponential function with base 10 and the exponent indicated in the EXP column. When not indicated, its value is 0. Valid values are as below:																									
	<table> <thead> <tr> <th>Value</th><th>Corresponding multiplier</th></tr> </thead> <tbody> <tr> <td>-2</td><td>10^{-2} (0,01)</td></tr> <tr> <td>-1</td><td>10^{-1} (0,1)</td></tr> <tr> <td>0</td><td>10^0 (1)</td></tr> <tr> <td>1</td><td>10^1 (10)</td></tr> <tr> <td>2</td><td>10^2 (100)</td></tr> </tbody> </table>	Value	Corresponding multiplier	-2	10^{-2} (0,01)	-1	10^{-1} (0,1)	0	10^0 (1)	1	10^1 (10)	2	10^2 (100)													
Value	Corresponding multiplier																									
-2	10^{-2} (0,01)																									
-1	10^{-1} (0,1)																									
0	10^0 (1)																									
1	10^1 (10)																									
2	10^2 (100)																									
M.U.	Unit of measurement of values when converted according to the rules indicated in columns CPL and EXP .
